**Pteromalidae (Insecta: Hymenoptera: Chalcidoidea) is one of the largest families of Chalcidoidea (Hymenoptera Parasitica), members of which are distributed in all the zoogeographical regions of the world. Majority of the species are primary or secondary parasitoids attacking other insect groups and some arachnida in their various stages of development (egg, pupa or larva). Some species are phytophagous, developing in seeds or making galls in plants. Adults are mostly metallic in colour having the size range of 1 – 48 mm (including ovipositor) and are free living, feeding on nectar. The females deposit their eggs inside the body of hosts with the help of specialized ovipositor. The eggs hatch inside the host's body and immature stages complete their development by consuming the contents of the body, thereby killing the host. They play a vital role in the control of insect pests and several species have been employed successfully in biological control programmes all over the world.**

**An adult Pteromalid wasp (Female)  
*Dinamrus maculatus* (Masi, 1925)**

**The family comprises of over 3500 described species under 588 genera world wide, out of which 224 species under 101 genera are reported from the Indian subcontinent (Noyes, 2003). The current check list includes 196 species under 91 genera reported so far from India.**
